

Running a maintenance stop

The tool is the record. What you do not enter did not happen as far as the customer's history goes — and what you do enter, they can be shown.

The stop, in order

- 1

Sign in
Shop passcode, once per phone per day. If it will not load at all, you are out of signal and out of a saved copy — open it once on Wi-Fi before you leave.
- 2

Pick the stop
Whole house or a single appliance. A whole-house stop compiles one review at the end; you do not build it yourself.
- 3

Serial-tag photo first
Required, every appliance, every visit. It is the one photograph that proves which machine was worked on, and it is what the age and tier come from.
- 4

Work the checks in order
Enter the numbers where a number is asked for — a rating with no reading behind it is the thing we are getting away from. If a reading cannot be taken, say why in the note. That is a real answer; a guess is not.
- 5

Photograph what you would want to prove
Coil before and after you clean it, and anything the customer will hear about. A finding with a photograph beside it never becomes an argument.
- 6

Complete, then check the photo line
Before the driveway: the tool says either **all photographs are on the shop machine** or how many are waiting. Waiting is fine, they go up on their own. Do not clear your browser while it still says waiting.

What we do not do

- ×

We never clean a grill. Not at maintenance, not on an unrelated call. Document the firebox and burners and move on; the report says on the finding itself that cleaning is not part of the plan.
- ×

No report tells a customer to replace anything. It can say a system is at 85% of expected life with two readings out of band — a fact they can plan around. The recommendation is a conversation, from you.
- ×

No prices, ever, on a health report. A number you did not quote is a number we have to defend later.
- ×

Nothing gets left on the generic checklist. If an appliance does not land in a category, tell Cayden what it was — that is a gap in the tool, not in you.

Numbers the tool judges today

Fresh food	typically 35–38°F against the set point
Freezer	typically near 0°F against the set point
Condenser TD	about 15–30°F above room ambient — take the room temperature too or there is nothing to compare
Oven accuracy	measured, no tolerance agreed yet
Dryer exhaust	measured, no target agreed yet
Microwave rise	measured, no defined load or time yet
Grill vs lid gauge	record both, note the disagreement

Where it says **no target agreed yet**, take the reading anyway. It is trended against this appliance's own history from the next visit on, and it is what the protocol meeting is settling.

HVAC

Nine readings	return & supply air, return & supply static, suction and liquid saturation and line temps, outdoor ambient, amps
Enter saturation as the gauge reads it	dew point on the suction side, bubble point on the liquid side. The tool has no refrigerant table and will not invent one
Static and amps	static against this blower's nameplate maximum, not a rule of thumb; amps against nameplate RLA
Charge	still your rating — superheat and subcooling bands are not set yet

A 14 SEER system in good condition scores like a system in good condition: efficiency and age are printed as facts and never move the score. Why did their older unit score well? Because it is in good shape, and we measured it.

When something goes wrong

- !

No signal. Keep working. Everything you enter is saved on the phone as you go, and the banner at the bottom says what is held there.
- !

Page will not load at all. That page has never been opened on this phone. Open the tool once on Wi-Fi at the shop and it keeps a copy from then on.
- !

Photos still waiting when you get back. The shop machine has to be running the tool for uploads to land. Tap **Try now** on the photo line once it is.
- ✓

A number looks wrong for the appliance. Enter what you measured, then say so in the note. A reading we argue with is worth ten we invented.
